Assume that a finite group G acts on a set Ω . An element $x \in \Omega$ is called a G -regular point if $|xG| = |G|$, i.e. if the stabilizer of x is trivial. Define the action of the group G on Ω^k by the rule

$$g : (i_1, \dots, i_k) \mapsto (i_1g, \dots, i_kg).$$

If G acts faithfully and transitively on Ω , then the minimal number k such that the set Ω^k contains a G -regular point is called the *base size* of G and is denoted by $b(G)$. For a positive integer m the number of G -regular orbits on Ω^m is denoted by $\text{Reg}(G, m)$ (this number equals 0 if $m < b(G)$). If H is a subgroup of G and G acts by the right multiplication on the set Ω of right cosets of H then G/H_G acts faithfully and transitively on the set Ω . (Here $H_G = \cap_{g \in G} H^g$.) In this case, we denote $b(G/H_G)$ and $\text{Reg}(G/H_G, m)$ by $b_H(G)$ and $\text{Reg}_H(G, m)$ respectively.

Thus $b_H(G)$ is the minimal number k such that there exist elements $x_1, \dots, x_k \in G$ for which $H^{x_1} \cap \dots \cap H^{x_k} = H_G$.

Consider the problem 17.41 from “Kourovka notebook” [1]:

Let H be a solvable subgroup of finite group G and G does not contain nontrivial normal solvable subgroups. Are there always exist five subgroups conjugated with H such that their intersection is trivial?

The problem is reduced to the case then G is almost simple in [2]. Specifically, it is proved that if for each almost simple group G and solvable subgroup H of G condition $\text{Reg}_H(G, 5) \geq 5$ holds then for each finite nonsolvable group G and solvable subgroup H of G condition $\text{Reg}_H(G, 5) \geq 5$ holds.

We have proved the following theorem

Theorem 1. *Let H be a solvable subgroup of an almost simple group G whose socle is isomorphic to A_n , $n \geq 5$. Then $\text{Reg}_H(G, 5) \geq 5$. In particular $b_H(G) \leq 5$.*
