Let  $K$  be a field of algebraic numbers with  $[K:\mathbb{Q}] < \infty$ , and let  $V^K$  be the set of all pairwise nonequivalent valuations of the field  $K$ .

Consider a square-free polynomial  $f(x) = x^{2n} + a_{2n-1}x^{2n-1} + \dots + a_0 \in K[x]$ . We set

$$D_f = K[x](\sqrt{f}) = \{\alpha + \beta\sqrt{f} \mid \alpha, \beta \in K[x]\}.$$

An element  $u \in D_f$  is called a unit if  $u$  is invertible in  $D_f$ . If  $u \in K^*$ , then  $u$  is called a trivial unit. Suppose that  $D_f$  has nontrivial units. Then,  $D_f^* = K^* \times \langle u_1 \rangle$ , where  $\langle u_1 \rangle$  is the infinite cyclic group. The element  $u_1$  is called the fundamental unit of  $D_f$ .

The problem of the existence of nontrivial units in  $D_f$  is difficult; it is deeply related to torsion in the Jacobian varieties of curves  $y^2 = f(x)$  and to continuous fractions in function fields (see [1]).

Suppose that  $v \in V^K$ ,  $\mathbf{O}_v$  is a valuation ring for non-Archimedean  $v$ ,  $\mathbf{p}_v$  is a maximal ideal in  $\mathbf{O}_v$ , and  $k_v = \mathbf{O}_v/\mathbf{p}_v$  is the residue field, being a finite field. For almost every  $v \in V^K$ , all coefficients of the polynomial  $f(x)$  belong to  $\mathbf{O}_v$ . Consider the polynomial  $f_v(x)$ , obtained from  $f(x)$  by reducing its coefficients modulo  $\mathbf{p}_v$ :  $f_v(x) \in k_v[x]$ .

It is easy to show that the polynomial  $f_v(x)$  is square-free for almost all  $v$ . Consider the ring

$$D_{f_v} = \{\alpha_v + \beta_v\sqrt{f_v(x)} \mid \alpha_v, \beta_v \in k_v[x]\}.$$

It is well known that  $D_{f_v}$  contains nontrivial units, so that  $D_{f_v}^* = k_v^* \times u_v$ , where  $u_v$  is the fundamental unit of  $D_{f_v}$ . If  $u_v = \alpha_v + \beta_v\sqrt{f_v}$ , then we set  $\deg u_v = \deg \alpha_v$ . In [1], the following local-global principle of a new type was established.

**Theorem 1.** *The ring  $D_f$  has a nontrivial unit if and only if there exists a constant  $C$  such that  $\deg u_v < C$  for almost all  $v \in V^K$ .*

The proof of this theorem uses properties of the Jacobian variety of the curve  $y^2 = f(x)$  and its localizations. At the end of paper [1], it was mentioned that, possibly, the methods of [2, 3] can be applied to the problem of the existence of nontrivial units.

The purpose of this paper is to present a fundamentally new proof of Theorem 1 using methods of [2] (a complete exposition is contained in [4]) and solve the problem of the existence and the determination of fundamental units for a large class of polynomials  $f$  with  $\deg f = 4$ . We do not employ Jacobian varieties.

The following assertion is valid for any field  $K$  of characteristic different from 2. We keep the notation for the polynomial  $f(x)$  and the ring  $D_f$  introduced above. Let  $|\cdot|_\infty$  be an infinite valuation on  $K(x)$ , and let  $\overline{K(x)}$  be the completion of  $K(x)$  with respect to  $|\cdot|_\infty$ . Any element  $z \in K(x)$  can be expanded in a Laurent series  $z = z_m x^m + z_{m-1} x^{m-1} + \dots$ , where  $z_i \in K$  and  $z_m \neq 0$ ; we have  $|z|_\infty = -m$ . Since the valuation  $|\cdot|_\infty$  admits two extensions to  $K(x)(\sqrt{f})$ , it follows that  $\sqrt{f} \in \overline{K(x)}$ . Consider  $\sqrt{f}$  the Laurent expansion

$$\sqrt{f} = x^s + d_{s-1}x^{s-1} + d_{s-2}x^{s-2} + \dots \quad (1)$$

and the matrix

$$H_r = \begin{pmatrix} d_{-1} & d_{-2} & \dots & d_{-r} \\ d_{-2} & d_{-3} & \dots & d_{-r-1} \\ \vdots & \vdots & \ddots & \vdots \\ d_{-r-s+2} & d_{-r-s+1} & \dots & d_{-2r-s+3} \end{pmatrix}. \quad (2)$$

This matrix has  $r$  columns and  $r+s-2$  rows. The following theorem is valid.

**Theorem 2.** *The ring  $D_f$  has a fundamental unit  $u = \alpha + \beta\sqrt{f}$ , where  $\alpha, \beta \in K[x]$  and  $\deg \beta = r$ , if and only if the rank of the matrix  $H_{r+1}$  is less than  $r+1$  and  $\text{rank } H_m = m$  if  $m < r+1$ . In this case,  $\deg u = r+s$ .*

**Proof.** Suppose that  $u = \alpha + \beta \sqrt{f}$  is a nontrivial unit in  $D_f$  and let

$$\alpha(x) = f_m x^m + f_{m-1} x^{m-1} + \dots + f_0,$$

$$\beta(x) = g_r x^r + g_{r-1} x^{r-1} + \dots + g_0,$$

where  $f_m \neq 0$  and  $g_r \neq 0$ . Since  $\alpha^2 - \beta^2 f \in K^*$ , it follows that  $m = r + s$  and

$$|\alpha + \beta \sqrt{f}|_\infty + |\alpha - \beta \sqrt{f}|_\infty = 0. \quad (3)$$

Consider  $\beta \sqrt{f}$  the Laurent expansion

$$\beta \sqrt{f} = h_m x^m + h_{m-1} x^{m-1} + \dots,$$

where  $h_i = \sum_{j+t=i} g_j d_t \in K$  and  $h_m \neq 0$ . Since  $f_m + h_m$  and  $f_m - h_m$  do not vanish simultaneously, it follows that the equalities  $|\alpha + \beta \sqrt{f}|_\infty = |\alpha - \beta \sqrt{f}|_\infty = 0$  cannot hold simultaneously either. For definiteness, suppose that  $|\alpha + \beta \sqrt{f}|_\infty > 0$  and  $|\alpha - \beta \sqrt{f}|_\infty < 0$ . Then, we have

$$f_m = h_m, \quad f_{m-1} = h_{m-1}, \dots, f_0 = h_0. \quad (4)$$

Moreover, (3) implies that  $|\alpha + \beta \sqrt{f}|_\infty = m$  and  $|\alpha - \beta \sqrt{f}|_\infty = -m$ . Therefore,

$$h_{-1} = h_{-2} = \dots = h_{-m+1} = 0.$$

This gives the system of equations

$$\begin{aligned} d_{-1}g_0 + d_{-2}g_1 + \dots + d_{-r-1}g_r &= 0, \\ d_{-2}g_0 + d_{-3}g_1 + \dots + d_{-r-2}g_r &= 0, \\ &\vdots \\ d_{-m+1}g_0 + d_{-m}g_1 + \dots + d_{-m-r+1}g_r &= 0. \end{aligned} \quad (5)$$

Let  $\mathbf{g} = (g_0, g_1, \dots, g_r)^t$ . Then, (5) can be written in the matrix form

$$H_{r+1}\mathbf{g} = 0. \quad (6)$$

Thus, the homogeneous system of linear equations (6) with matrix  $H_{r+1}$  has a nonzero solution  $\mathbf{g}$ , and the rank of the matrix  $H_{r+1}$  is less than  $r+1$ .

Conversely, suppose that the rank of the matrix  $H_{r+1}$  is less than  $r+1$ . Then, the homogeneous system of linear equations (6) has a nonzero solution  $\mathbf{g}$ , and  $g_r \neq 0$  for this solution. Let us calculate the coefficients of the polynomial  $f$  by formulas (4). By construction, we have  $|\alpha + \beta \sqrt{f}|_\infty = m$  and  $|\alpha - \beta \sqrt{f}|_\infty = -m$ . Therefore,

$$|\alpha^2 - \beta^2 f|_\infty = |\alpha + \beta \sqrt{f}|_\infty + |\alpha - \beta \sqrt{f}|_\infty = 0.$$

Since  $\alpha^2 - \beta^2 f \in K[x]$ , it follows that  $\alpha^2 - \beta^2 f \in K^*$ , and hence,  $u = \alpha + \beta \sqrt{f}$  is a nontrivial unit of the ring  $D_f$ . By construction,  $\deg \beta = r$ ; thus,  $\deg u = r+s$ .

Note that, to obtain the fundamental unit of the ring  $D_f$ , it suffices to find the least positive integer  $r$  for which the rank of the matrix  $H_r$  is less than  $r$ .

In what follows, we again assume that  $K$  is a field of algebraic numbers. Let us derive Theorem 1 from Theorem 2.

Suppose that  $u = \alpha + \beta \sqrt{f}$  is a nontrivial unit in  $D_f$ . Let  $S$  denote the set of valuations  $v \in V^K$  such that all coefficients of the polynomials  $f(x)$ ,  $\alpha(x)$ , and  $\beta(x)$  belong to  $\mathbf{O}_v$ , the polynomial  $f_v(x)$  is square-free, and the characteristic of the field  $k_v$  is different from 2. Clearly, the set  $V^K \setminus S$  is finite. Since  $\alpha^2 - \beta^2 f \in K^*$ , it follows that  $\alpha_v^2 - \beta_v^2 f_v \in k_v^*$  for any  $v \in S$ . This means that the element  $u'_v = \alpha_v + \beta_v \sqrt{f_v}$  is a unit of the ring  $D_{f_v}$ . Clearly,  $\deg u'_v \leq \deg u$ . The fundamental unit  $u_v$  of the ring  $D_{f_v}$  satisfies the relations  $\deg(u_v) \leq \deg(u'_v) \leq \deg(u)$ ; thus, for the constant  $C$  we can take  $\deg(u)$ .

Let us prove the converse. Suppose that  $\deg u_v < C$  for all  $v \in S$ . Take an arbitrary  $v \in S$ . Let  $\overline{k_v(x)}$  be the completion of the field  $k_v(x)$  with respect to the infinite valuation  $|\cdot|_\infty$ . Since  $\sqrt{f_v} \in \overline{k_v(x)}$ , we can expand  $\sqrt{f_v}$  in a Laurent series as

$$\sqrt{f_v} = x^s + (d_{s-1})_v x^{s-1} + (d_{s-2})_v x^{s-2} + \dots,$$

where the coefficients  $(d_i)_v$  are the reductions of the coefficients  $d_i$  in decomposition (1) modulo  $\mathbf{p}_v$ . Let  $H_{r,v}$  denote the matrix obtained from the matrix  $H_r$  by reducing its elements modulo  $\mathbf{p}_v$ . Since the ring  $D_{f_v}$  has the nontrivial fundamental unit  $u_v$ , Theorem 2 implies the existence of a positive integer  $r = r(v)$  for which the rank of the matrix  $H_{r,v}$  is less than  $r$ . This means that all minors of order  $r$  in the matrix  $H_{r,v}$  vanish. Moreover, we have  $\deg(u_v) = r(v) + s - 1$ . Using the assumptions of the theorem, we obtain  $r(v) \leq C - s + 1$ .

Since the set  $S$  infinite, it contains an infinite subset  $S_1 \subset S$  such that  $r(v_1) = r(v_2)$  for any  $v_1, v_2 \in S_1$ . Let  $v \in S_1$ . Consider any minor  $T$  of order  $r$  in the matrix  $H_r$  and the corresponding minor  $T_v$  in the matrix  $H_{r,v}$ . Clearly,  $T_v$  is obtained from  $T$  by reduction modulo  $\mathbf{p}_v$ . As mentioned above,  $T_v = 0$  for all  $v \in S_1$ . By virtue of the infinity of  $S_1$ , this implies  $T = 0$ . Thus, all minors of order  $r$  in the matrix  $H_r$  vanish. Therefore, the rank of this matrix is less than  $r$ , and Theorem 2 implies the existence of a nontrivial unit in the ring  $D_f$ . This completes the proof of Theorem 2.

An algorithmic solution of the problem of the existence of nontrivial units in the ring  $D_f$  for polynomials  $f$  with  $\deg f \leq 4$  was obtained in [1] by reducing the problem under consideration to the problem of torsion in elliptic curves. For the case  $K = \mathbb{Q}$ , an important observation was made in [1]: the degree of the fundamental unit is at most 12 and cannot equal 11. This opens a way to a fast direct calculation of nontrivial

units. In the case of  $\deg f = 4$ , the matrix  $H_r$  defined by (2) is Hankel, and the condition  $\text{rank } H_r < r$  is equivalent to  $\det H_r = 0$ .

In [1], a question of F. Grunewald was answered; namely, it was proved that the ring  $D_f$  for the polynomial  $f(x) = x^4 + x + 1$  contains no nontrivial units. Moreover, it was mentioned in [1] that if  $f(x) = x^4 + c$  or  $f(x) = x^4 + x$ , then the corresponding ring  $D_f$  has nontrivial units.

Using the methods developed in this paper, we can give a complete answer to the question of for what polynomials  $f(x) = x^4 + bx + c$  the ring  $D_f$  has nontrivial units.

**Theorem 3.** *For a polynomial of the form  $f(x) = x^4 + bx + c$ , the ring  $D_f$  has a fundamental unit of degree  $n$  at the following  $n$ ,  $b$ , and  $c$ :*

- (i)  $n = 2$ ,  $b = 0$ ,  $c \in \mathbb{Q}^*$ ,  $u = x^2 + \sqrt{f}$ ;
- (ii)  $n = 3$ ,  $c = 0$ ,  $b \in \mathbb{Q}^*$ ,  $u = x^3 + \frac{b}{2} + x\sqrt{f}$ ;
- (iii)  $n = 4$ ,  $b = t^3$ ,  $c = \frac{t^4}{2}$ , where  $t \in \mathbb{Q}^*$ ,  $u = x^4 - tx^3 + \frac{t^2}{2}x^2 + \frac{t^3}{2}x - \frac{t^4}{4} + \left(x^2 - tx + \frac{t^2}{2}\right)\sqrt{f}$ .

**Proof.** The Laurent expansion of  $\sqrt{f}$  has the form

$$\begin{aligned} \sqrt{f} = & x^2 + \frac{1}{2}bx^{-1} + \frac{1}{2}cx^{-2} - \frac{1}{8}b^2x^{-4} - \frac{1}{4}bcx^{-5} \\ & - \frac{1}{8}c^2x^{-6} + \frac{1}{16}b^3x^{-7} + \frac{3}{16}b^2cx^{-8} + \dots, \end{aligned}$$

where the coefficients  $d_{-i}$  of  $x^{-i}$  are calculated by the recursive formulas

$$\begin{aligned} d_{-(2m+1)} &= -d_{-1}d_{-2m} - \dots - d_{-m}d_{-m-1}, \\ d_{-2m} &= -d_{-1}d_{-2m+1} - \dots - d_{-m+1}d_{-m-1} - \frac{1}{2}d_{-m}^2. \end{aligned}$$

By Theorem 2, the ring  $D_f$  has a nontrivial unit  $u$  of degree  $r+1$  if and only if  $\det H_r = 0$ .

For  $r = 1$ , we have  $\det H_r = \frac{b}{2} = 0$ ; therefore,  $f(x) = x^4 + c$ . This case was considered in [1]. Obviously, the element  $u = x^2 + \sqrt{f}$  is the fundamental unit of the ring  $D_f$ .

For  $r = 2$ , we have  $\det H_r = -\frac{c^2}{4} = 0$ . Therefore,  $f(x) = x^4 + bx$ . In this case, the fundamental unit of the ring  $D_f$  has the form  $u = x^3 + \frac{b}{2} + x\sqrt{f}$ .

For  $r = 3$ , we have  $\det H_r = \frac{1}{128}b(-b^4 + 9c^3) = 0$ .

The case  $b = 0$  was considered above. It is easy to show that the equation  $-b^4 + 8c^3 = 0$  has the rational solu-

tions  $b = t^3$ ,  $c = \frac{t^4}{2}$ , where  $t \in \mathbb{Q}^*$ . The fundamental unit of the ring  $D_f$  has the form

$$u = x^4 - tx^3 + \frac{t^2}{2}x^2 + \frac{t^3}{2}x - \frac{t^4}{4} + \left(x^2 - tx + \frac{t^2}{2}\right)\sqrt{f}.$$

Note that, for any  $t \in \mathbb{Q}^*$ , the elliptic curve  $y^2 = f(x)$  is biregularly isomorphic to the curve  $y_1^2 = f_1(x)$ , where  $f_1(x) = x_1^4 + x_1 + \frac{1}{2}$ . The corresponding morphism is determined by  $x = tx_1$ ,  $y = t^2y_1$ .

For  $r = 4$ , we have

$$\det H_r = \frac{1}{256} \left( c^6 + \frac{1}{2}c^3b^4 - \frac{1}{16}b^8 \right) = 0. \quad (7)$$

Making the change of variables  $z = \frac{c^3}{b^4}$ , we can rewrite Eq. (7) in the form

$$h_r(z) = z^2 + \frac{1}{2}z - \frac{1}{16} = 0. \quad (8)$$

Since the polynomial  $h_r(z)$  in (8) has no rational roots, it follows that Eq. (7) has no rational solutions  $b$ ,  $c$ . Thus, there exist no polynomials  $f(x)$  for which the ring  $D_f$  has a fundamental unit of degree  $n = r+1 = 5$ .

A similar calculation shows that, for  $r = 5, 6, 7, 8, 9, 11$ , the element  $z = \frac{c^3}{b^4}$  is a root of the corresponding polynomial  $h_r(z)$ , which is defined for these  $r$  by

$$\begin{aligned} h_5(z) &= 24z^2 - 12z + 1, \\ h_6(z) &= z^4 + \frac{5}{2}z^3 - \frac{13}{16}z^2 + \frac{3}{32}z - \frac{1}{256}, \\ h_7(z) &= 512z^4 - 640z^3 + 16z - 1, \\ h_8(z) &= 4096z^6 + 30720z^5 - 19200z^4 \\ &\quad + 6528z^3 - 1152z^2 + 96z - 3, \\ h_9(z) &= 20480z^6 - 73728z^5 + 35584z^4 \\ &\quad - 7040z^3 + 720z^2 - 40z + 1, \\ h_{11}(z) &= 32768z^8 - 18024z^7 - 225280z^6 \\ &\quad + 114688z^5 - 29440z^4 + 5440z^3 - 640z^2 + 40z - 1. \end{aligned}$$

The polynomials  $h_r(z)$  with  $r \geq 5$  are irreducible over  $\mathbb{Q}$ , and therefore, they have no rational roots. Hence, there exists no polynomial  $f(x) = x^4 + bx + c$  for which the ring  $D_f$  has a fundamental unit of degree  $n \geq 5$ . This completes the proof of Theorem 3.

In the proof of Theorem 3, the calculation of the determinants  $\det H_r$ , the factorization of polynomials, and the proof of the irreducibility over  $\mathbb{Q}$  of the polynomials  $h_r(z)$  with  $r \geq 5$  were performed by using the Maple computer algebra system.
